Outline

1. BRAHMS experimental setup
2. Introduction: some lessons from BRAHMS
 - a) produced and “primary” matter
 - b) hadron chemistry
3. Recent results and model comparisons on baryons stopping and proton to pion ratios
4. Summary

Relativistic Heavy Ion Collider w BNL

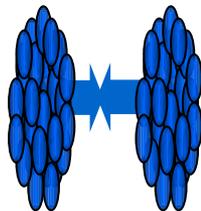

Energies:

$$\sqrt{s_{NN}} = 62 \text{ GeV},$$

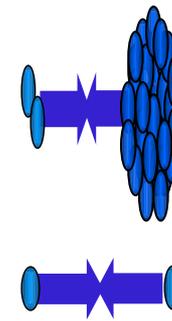

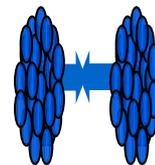

$$\sqrt{s_{NN}} = 130 \text{ GeV},$$

$$\sqrt{s_{NN}} = 200 \text{ GeV}$$

Au+Au

Cu+Cu

d+Au

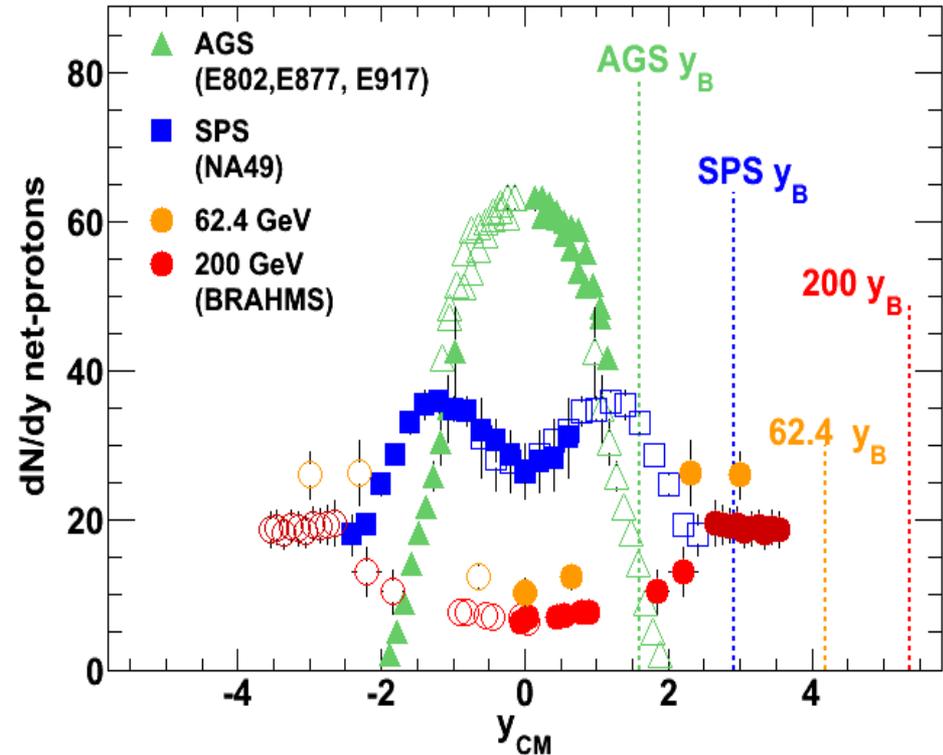

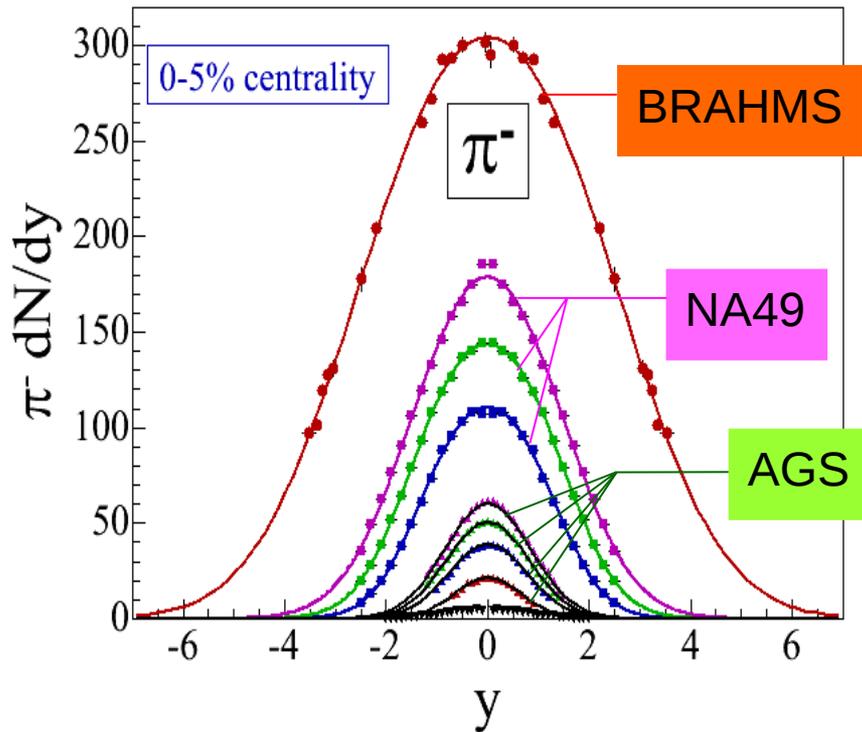

p+p

Particle production versus stopping

Produces matter peaks at $y=0$, this matter is charge symmetric. No significant change is shape from AGS to RHIC

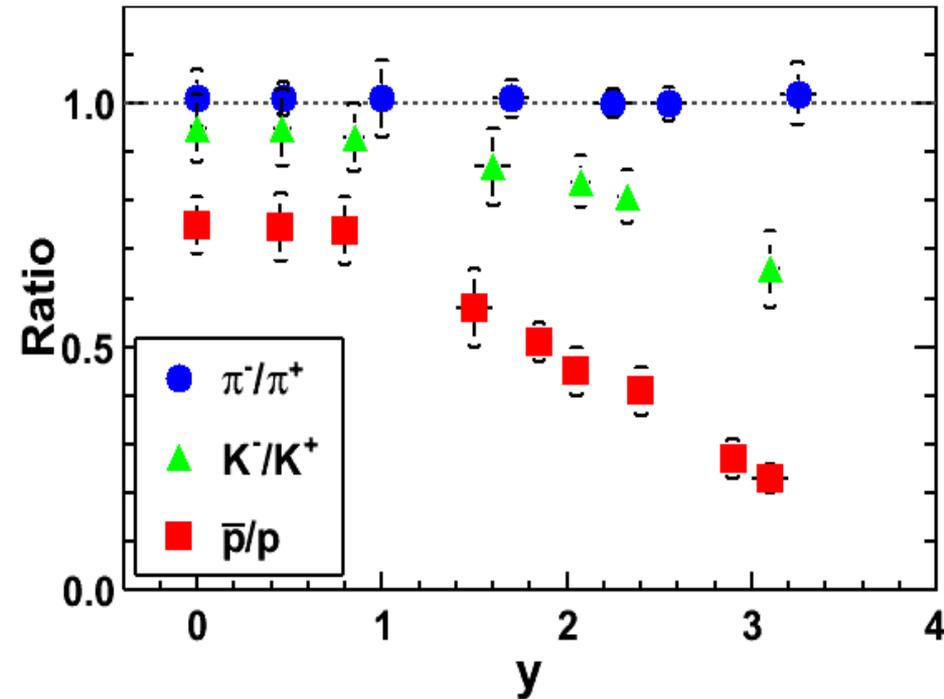

Primary matter: evolution from lower to higher energies. At mid rapidity evolution from baryon (AGS) to meson (RHIC) dominated medium

$$\sqrt{s_{NN}} = 4.7 \text{ 17.3 } 200 \text{ GeV}$$

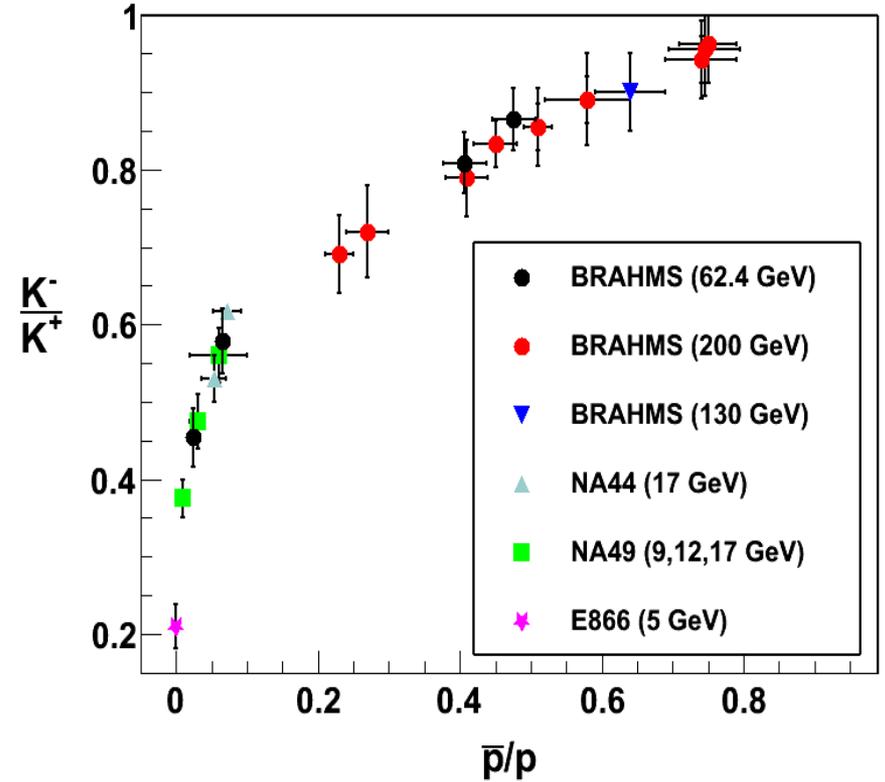

Particle ratios and hadron chemistry

central Au + Au at 200 GeV

Proton and kaon ratios decreases towards forward rapidity

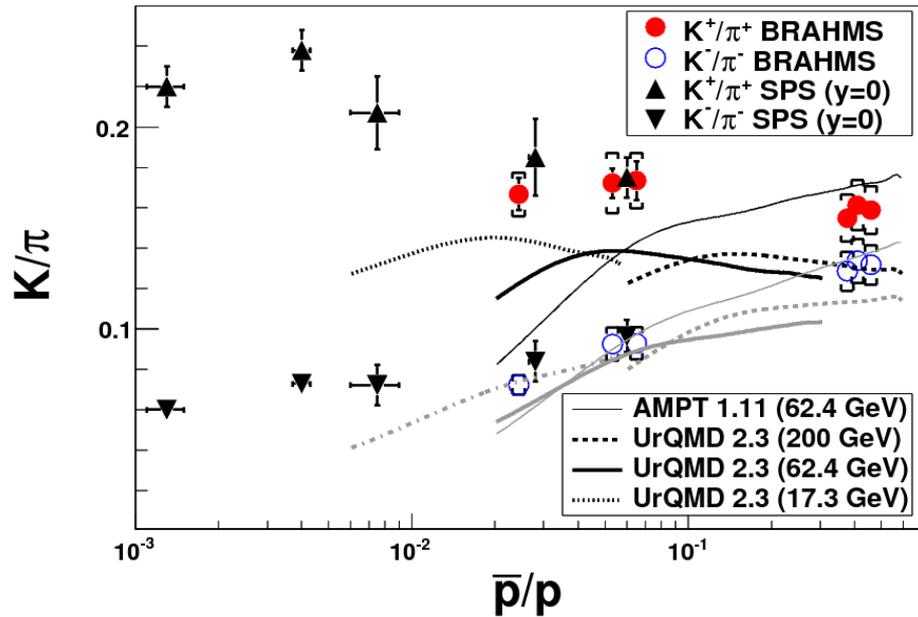

Pion ratios are consistent with unity

Correlation between the BRAHMS kaon and proton ratios over 3 units of rapidity.

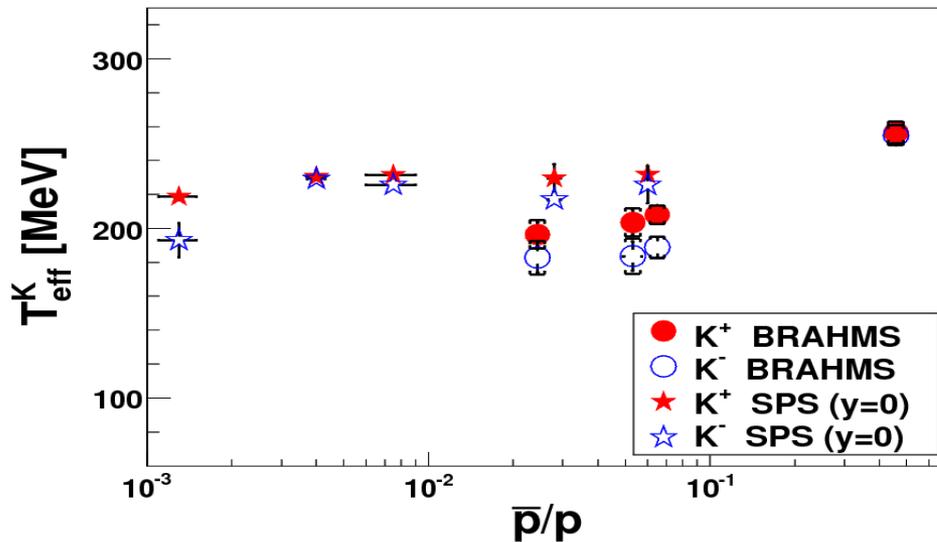

Forward rapidity 62.4 GeV data overlap with mid-rapidity data from SPS

Particle ratios and hadron chemistry

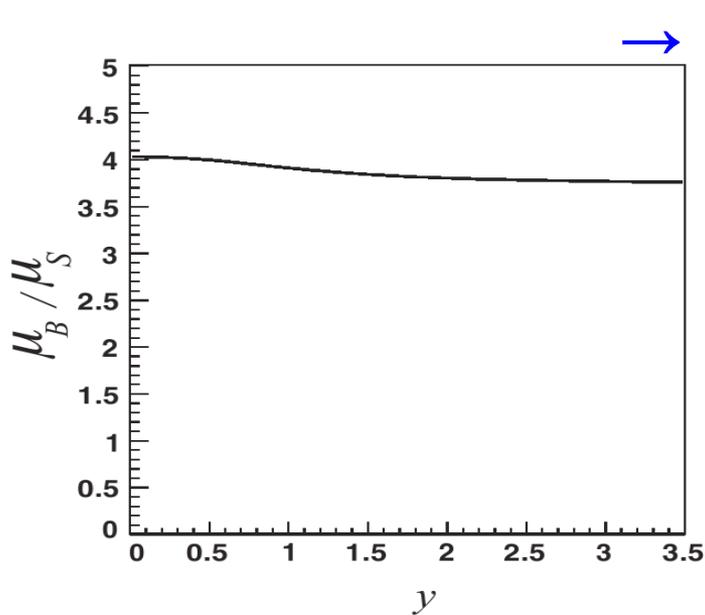

Forward rapidity K/π ratios measured at 62 GeV overlap with the same ratios measured at SPS

As you can see the models that we had tried can not described that effect. **PLB 867 (2010) 36**

However, the systems have different sizes. The softer kaon spectra suggest that the radial expansion is slower for the forward RHIC collisions

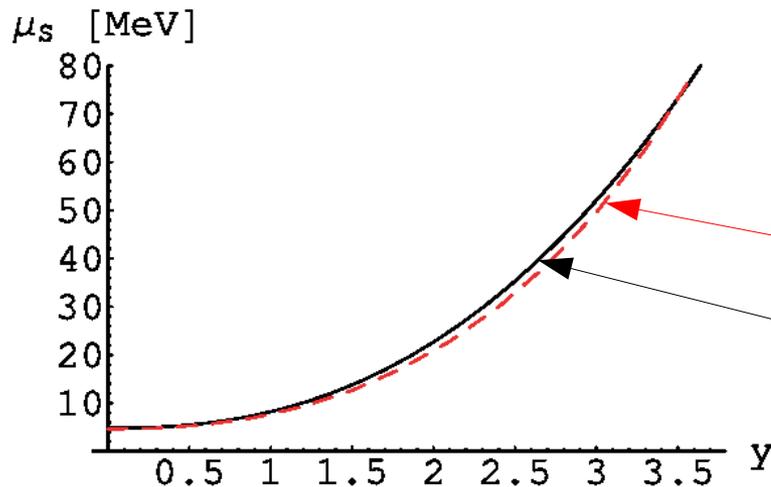

Statistical model fit to BRAHMS data

μ_s versus μ_B

Fits with statistical model provide μ_B / μ_S ratio with weak dependency on y .

B. Bieron and W. Broniowski Phys. Rev. C75 (2007) 054905

This result is consistent with local net-strangeness conservation

red line - $\rho_{s-sbar} = 0$

black line - fit to BRAHMS data

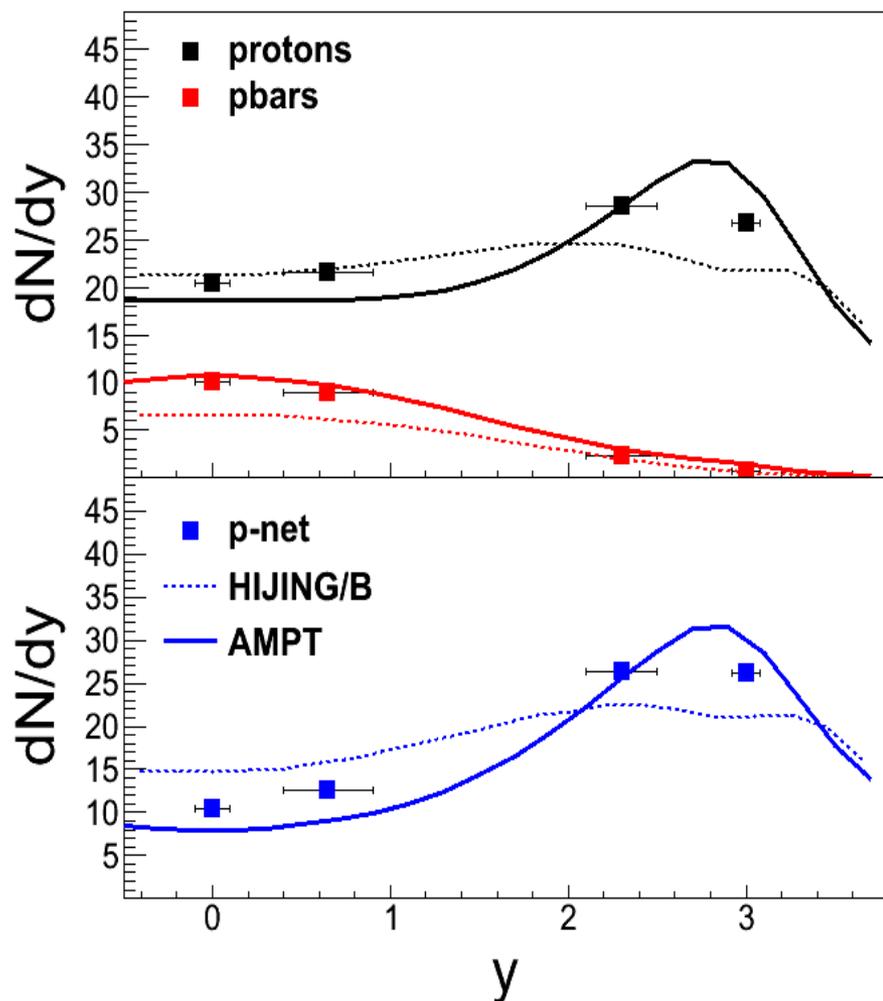

Baryon transport – short review

As I tried to explain the baryon stopping determines density and chemical composition of the produced media in high energy A+A collisions.

- Standard mechanism used for description of baryon transport is breaking of $q - qq$ configuration. In this case the baryon number is associated with valence quarks.
- However this mechanism alone is not able to move net-baryon number over a large range of rapidity.
- ISR pp and HERA (non-zero baryon asymmetry of $\approx 8\%$ in γp reactions at more than 8 units of rapidity) demonstrated that additional mechanisms with a slower y dependence are needed to account for the data. Baryon junctions is one mechanism that can move baryon number over a large rapidity range

Stopping 62 GeV

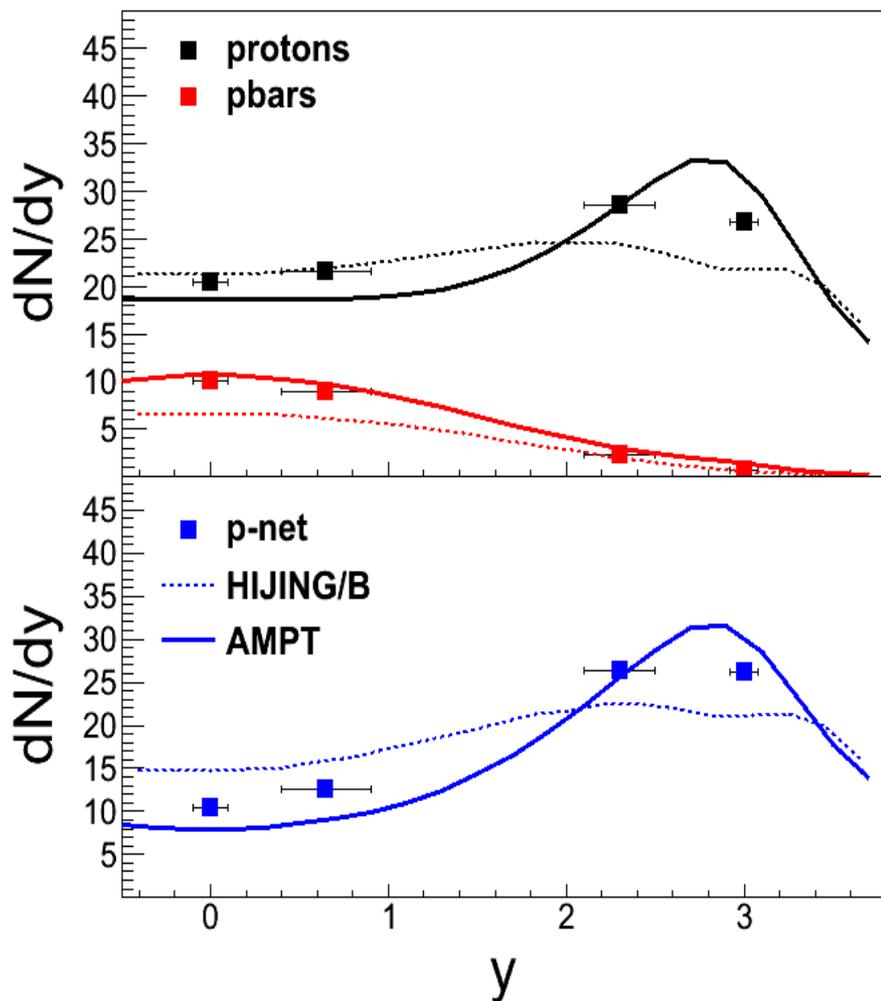

Measurement from $y = 0$ to ~ 3
overlaps fragmentation region ($y_b = 4.2$)

PLB 677 (2009) 267

AMPT model incorporates q-qq
breaking mechanism \rightarrow over all good
description but it underestimates net-
protons at mid-rapidity

HIJING/B incorporates baryon
junctions to can account for the large
stopping. Parameters tuned to data
from SPS. **PLB 443 (1998) 45**

Stopping 62 GeV

AMPT model incorporates q-qq
breaking mechanism \rightarrow over all good
description but it underestimates net-
protons at mid-rapidity

HIJING/B incorporates baryon
junctions to can account for the large
stopping. Parameters tuned to data
from SPS. **PLB 443 (1998) 45**

Stopping at 200 GeV

AMPT does quite a good job for peripheral Au+Au at 200 GeV, it however can not describe data for central reactions.

Hijing/B seems to reproduce the trend with centrality, however, it tends to overestimates net-proton data for more central reactions.

Proton to pion ratios vs y and p_T

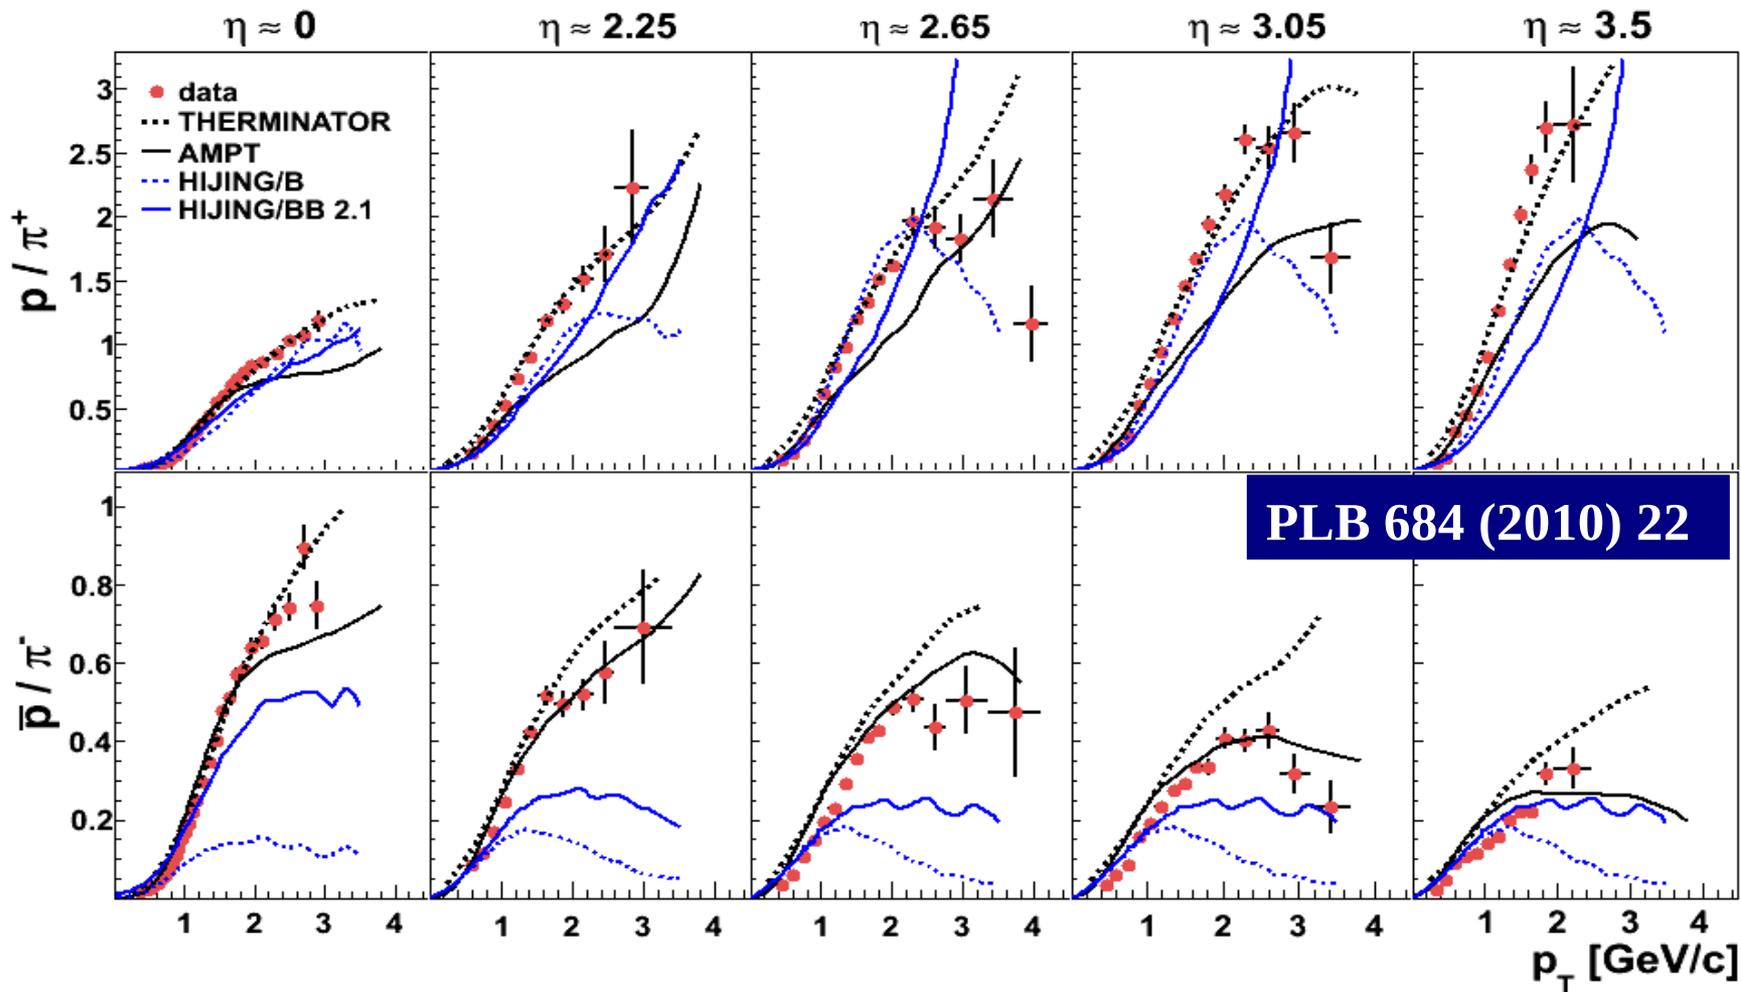

Mechanisms responsible for the baryon stopping determine also the energy dissipation in the collision
→ pion production.

Mechanisms like baryon junction and baryon junction loops (JJbar loops included in HIJING/BBbar1.0 and 2.1) incorporate transverse baryon dynamics.

This is all reflected in p_T and rapidity dependence of p/π ratios

ρ/π ratios vs y and p_T

Summary

- Brahmans provide measurement of baryon number transport in the p+p and Au+Au reactions at RHIC energies
- Net-p measured in p+p are consistent with quark – di-quark breaking mechanism
- Au+Au data suggest additional mechanisms for baryon transport. (baryon junction, popcorn, di-quark breaking)
- To disentangle between different scenarios one has to study transverse dynamics of the baryon number transport
- There is no model on the market which could simultaneously describe all available data (net-protons and p/π ratios, hyperon spectra)

Predictive power of $\mu_s \approx 1/4 \mu_B$

We have good description of kaon data

$$\mu_s \approx 1/4 \mu_B \rightarrow$$

$$K^-/K^+ = (\bar{p}/p)^{1/4}$$

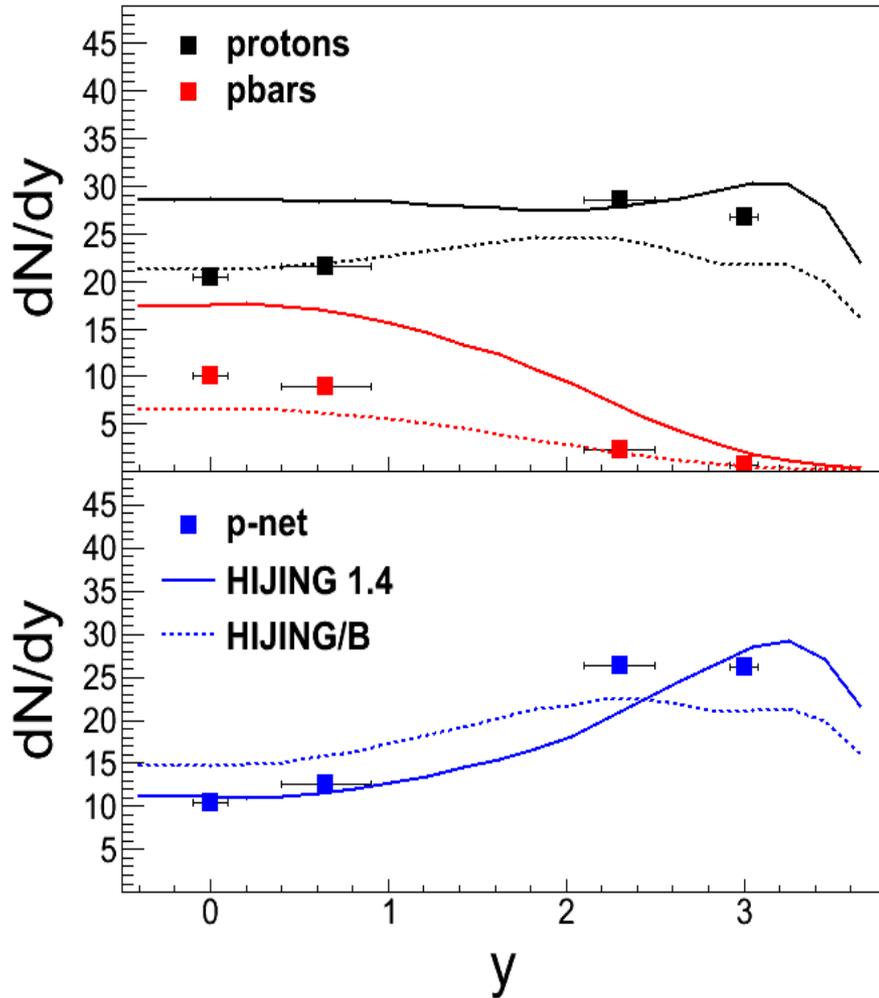

How $\mu_s \approx 1/4 \mu_B$ will work for hyperons?

$$Hbar/H = (\bar{p}/p)^{3/4} \quad \text{for } \Lambda$$

$$= (\bar{p}/p)^{1/2} \quad \text{for } E$$

$$= (\bar{p}/p)^{1/4} \quad \text{for } \Omega$$

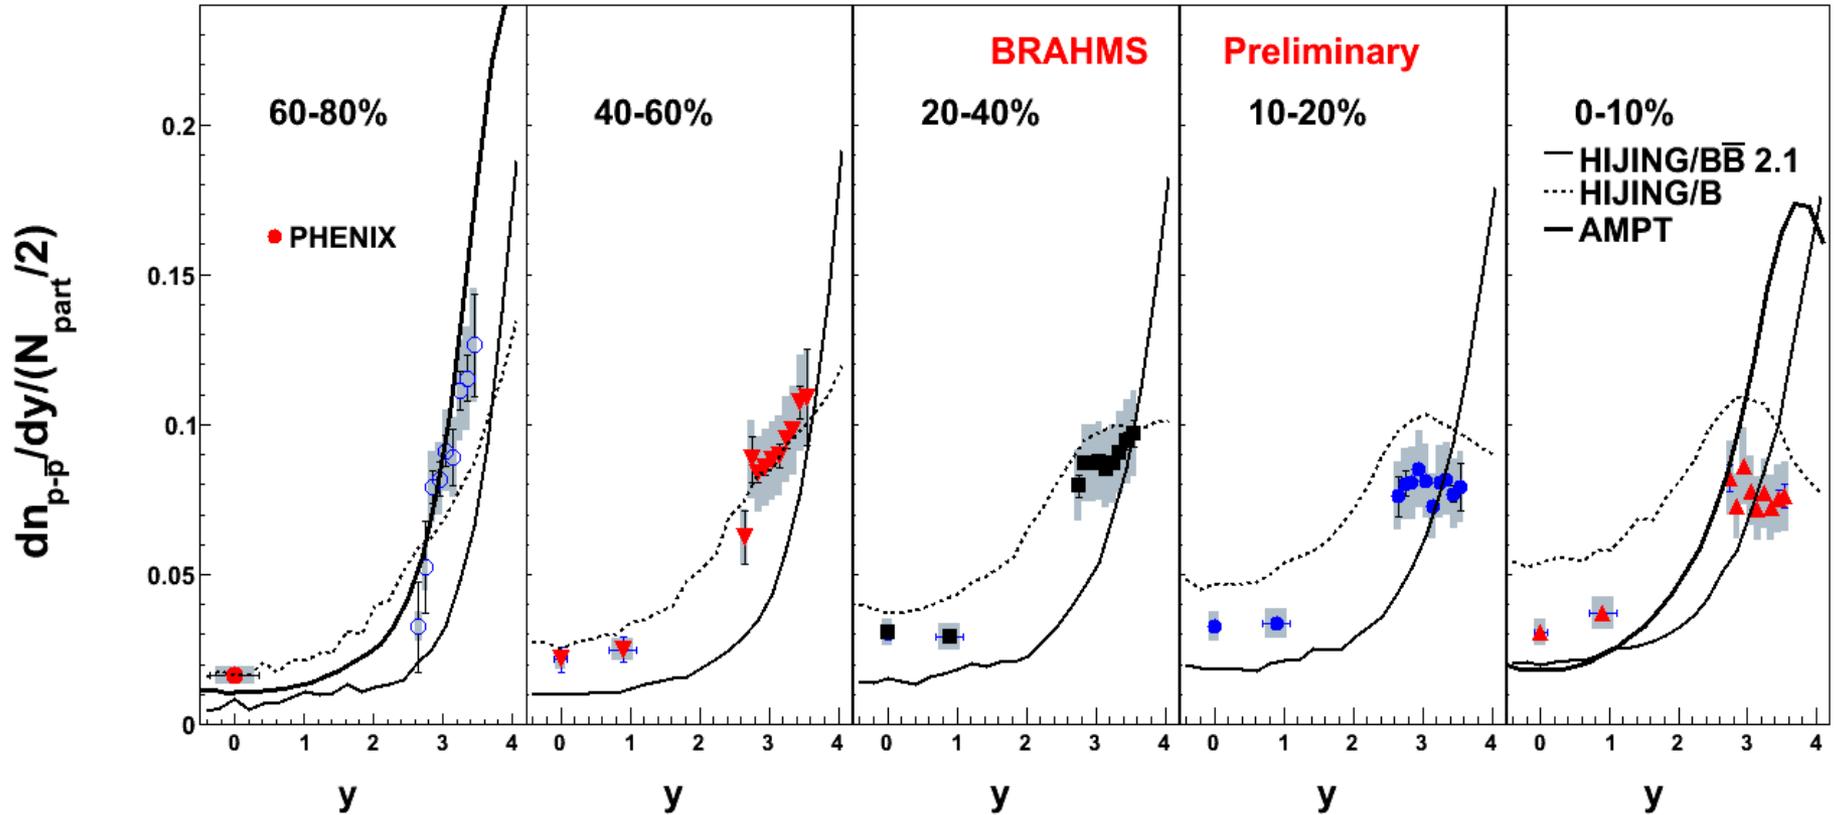

Stopping 62 GeV

Incidentally pure HIJING (without the junction) can describe the net- p at $y \sim 0$ but underestimates the experimental $\langle \Delta y \rangle$.

It also significantly overestimates Production of protons and anti-protons

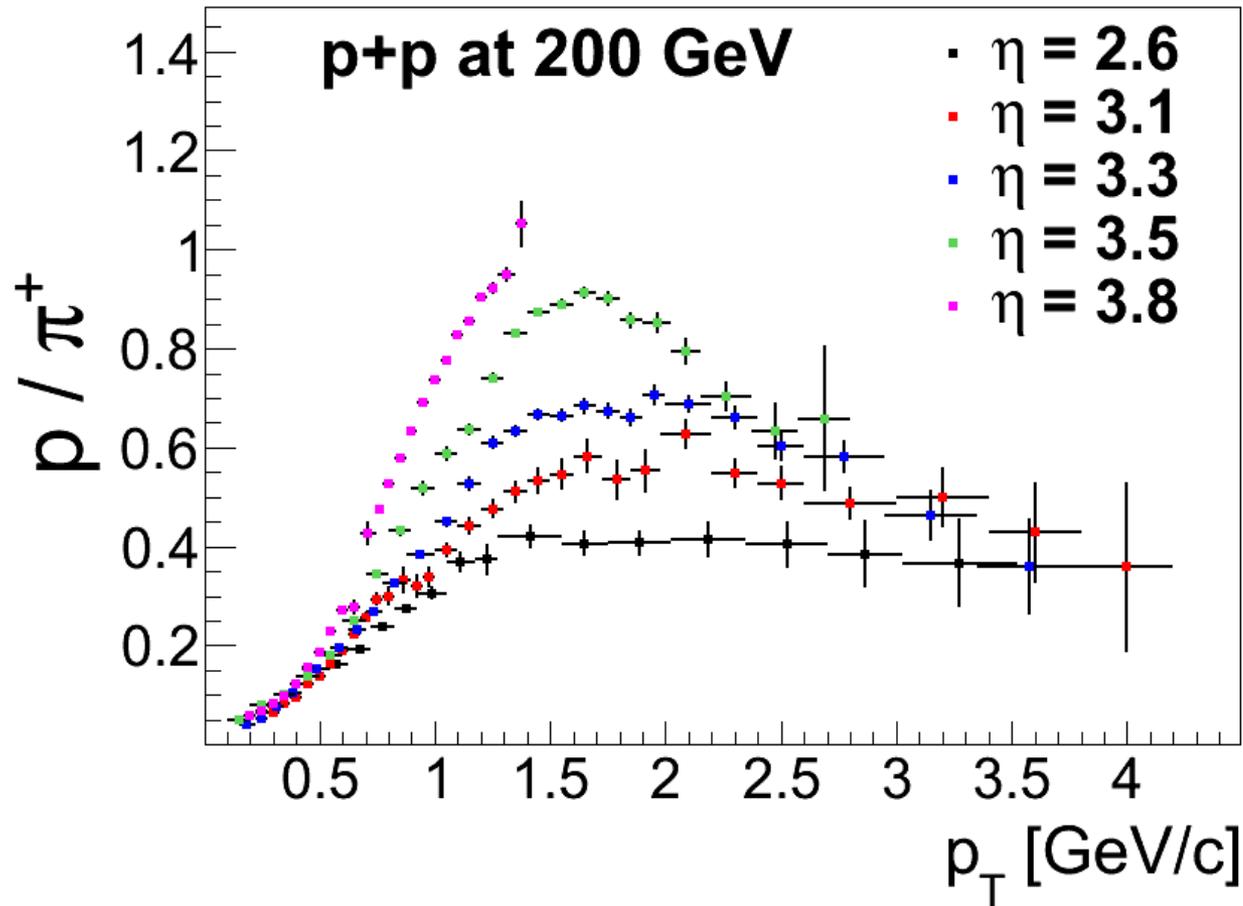

Stopping at 200 GeV

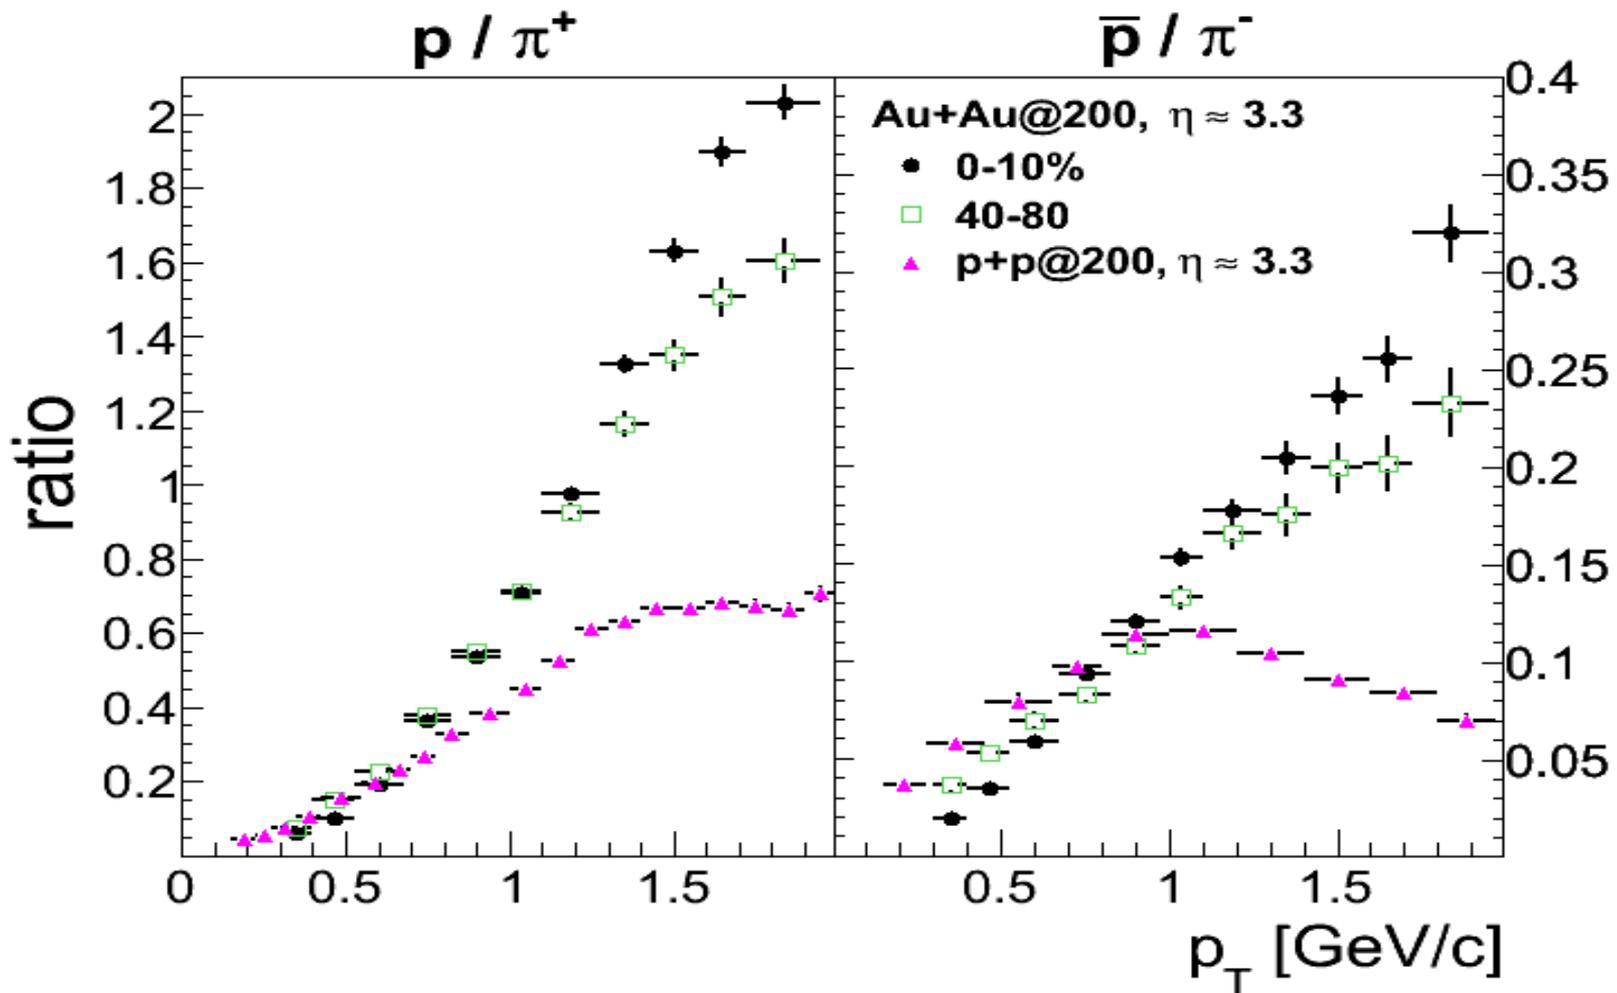

Hijing/BBbar 2.1: modified baryon junction phenomenology to account for better description of hyperon m_T spectra. **PRC 70 (2004) 064906**

This version fails to description of stopping

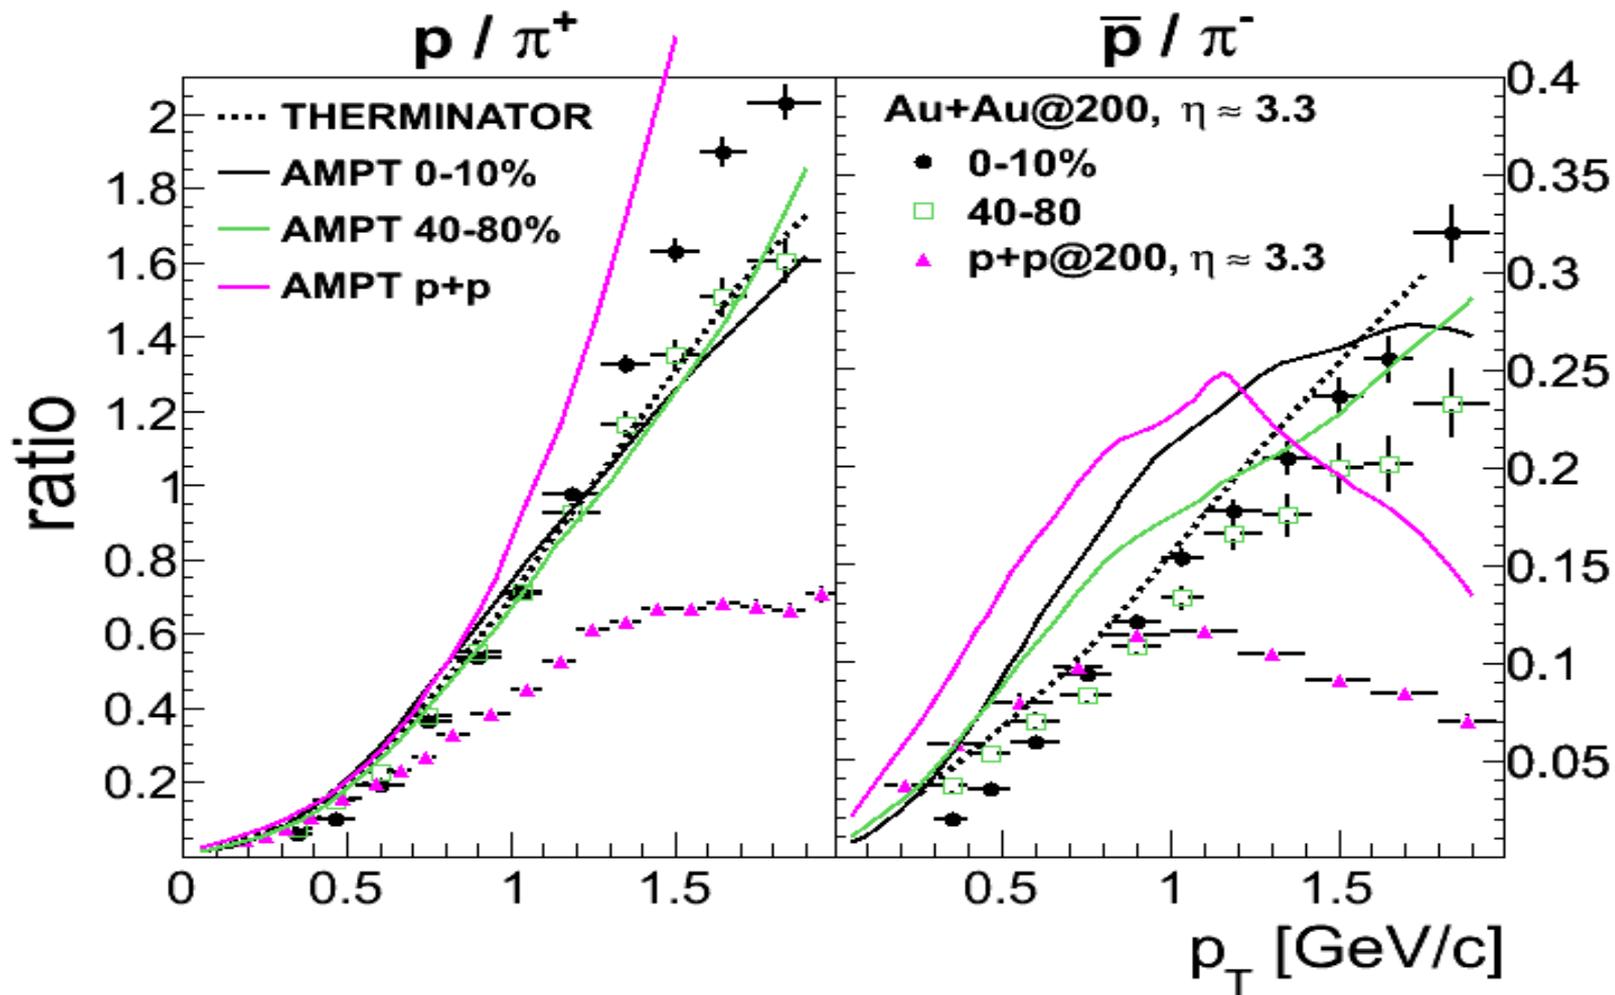

Results: p+p at 200 GeV versus rapidity

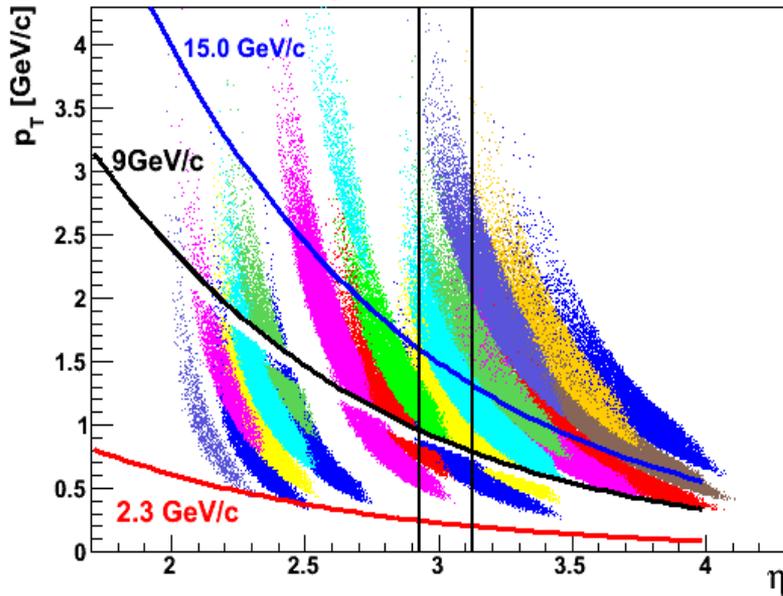

Results: Au+Au and p+p at 200 GeV at low p_T

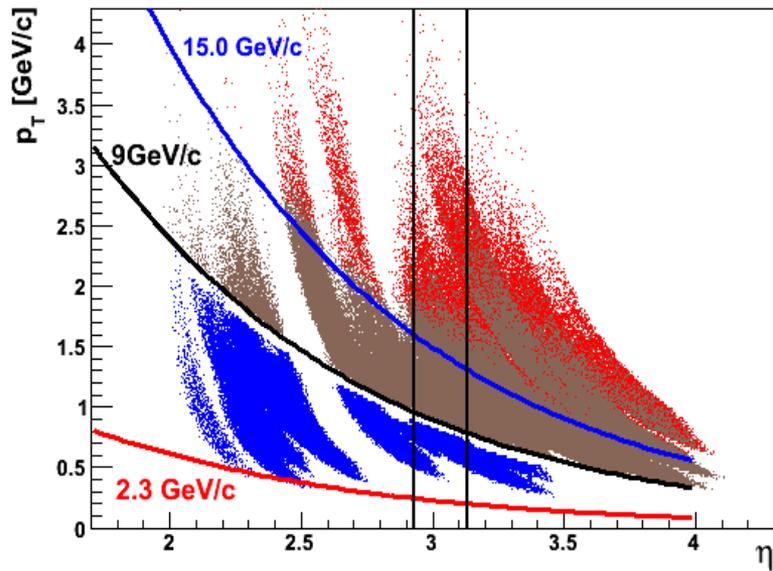

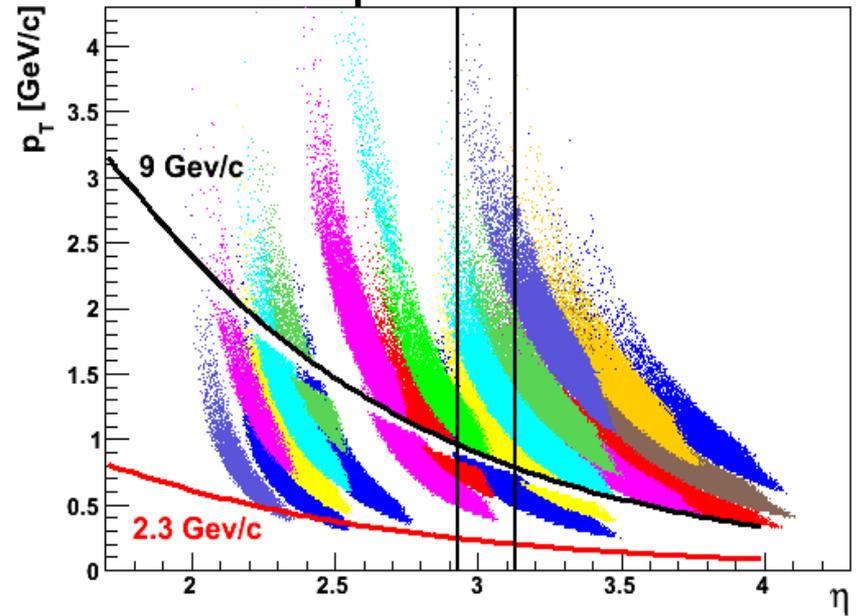

Results: Au+Au and p+p at 200 GeV at low p_T

protons

pions

Same acceptance for pions and protons in the real time measurements. For given η - p_T bin p/π ratio is calculated on setting by setting basis using same pid technique:

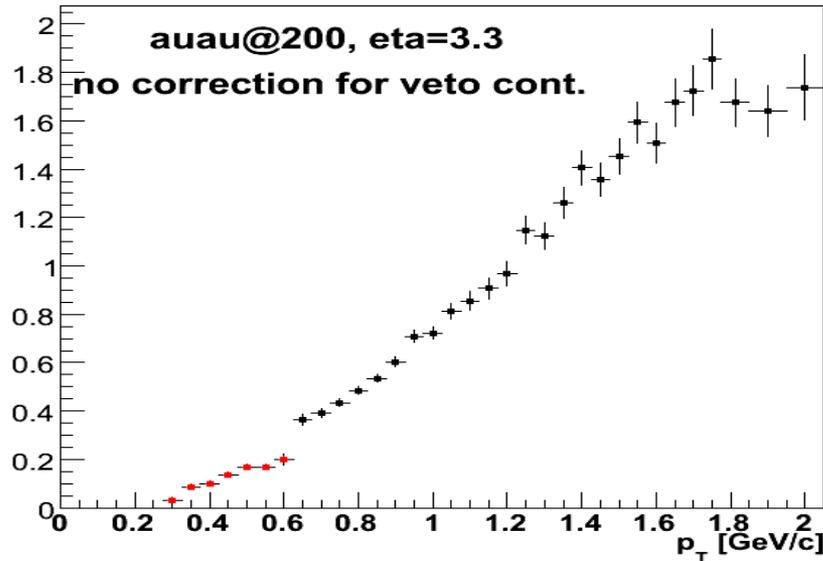

Tof2: 2.3->~8 GeV/c, RICH: above 9 GeV/c, thus acceptance corrections, tracking efficiency trigger normalization canceled out in the ratio.

Remaining corrections:

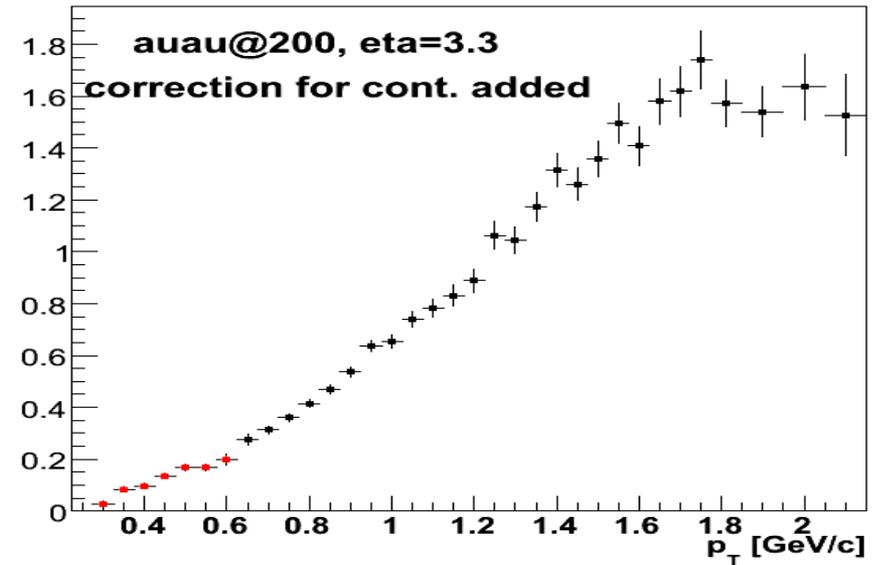

- decay in flight, interaction in beam pipe and material budget (GEANT calculation)
- correction for PID efficiency and contamination (limited specie resolution)

Test of corrections for veto-protons

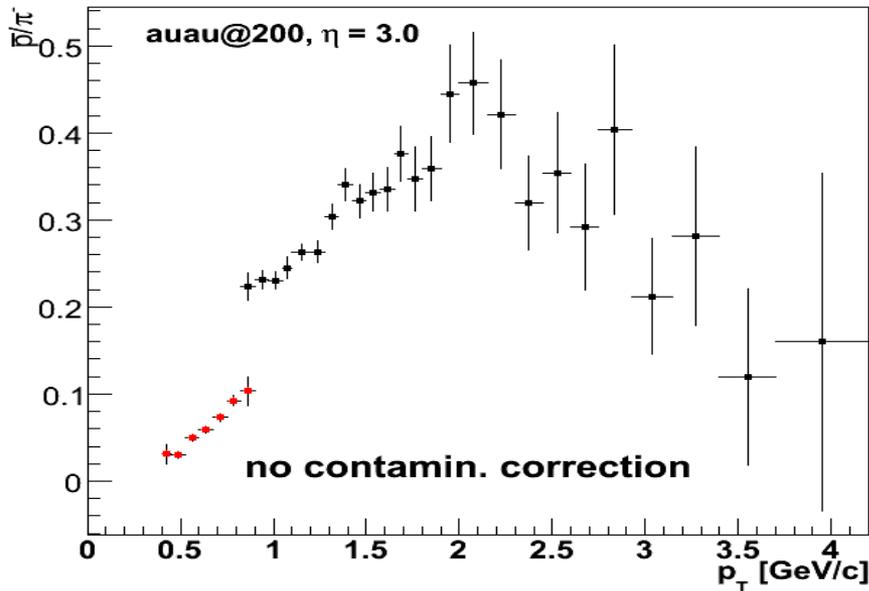

pions

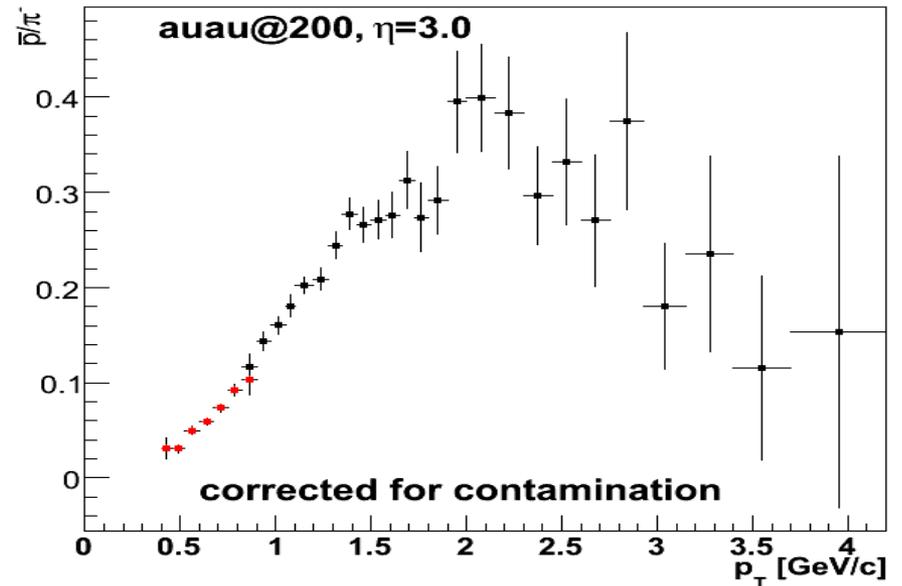

pions

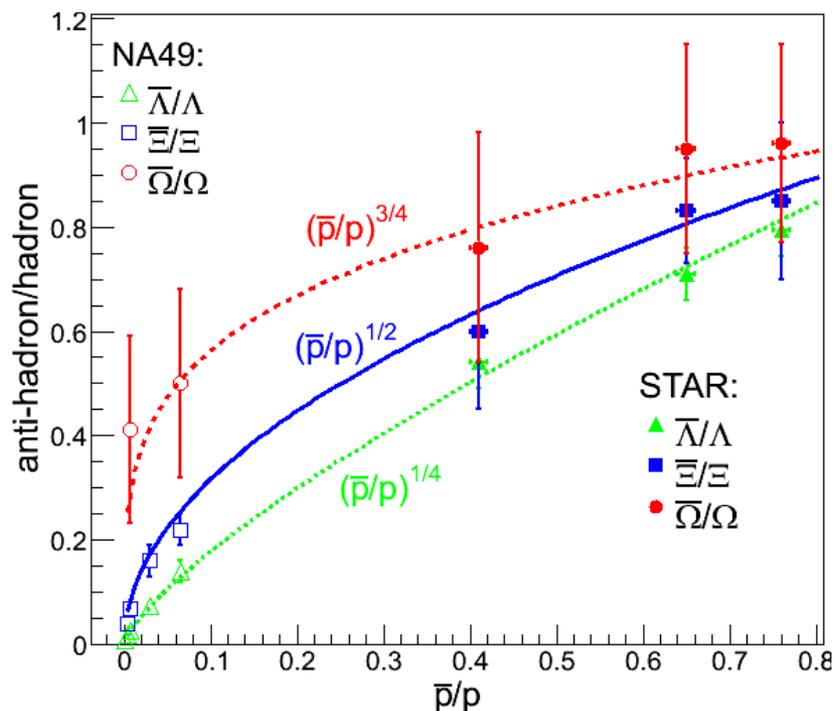

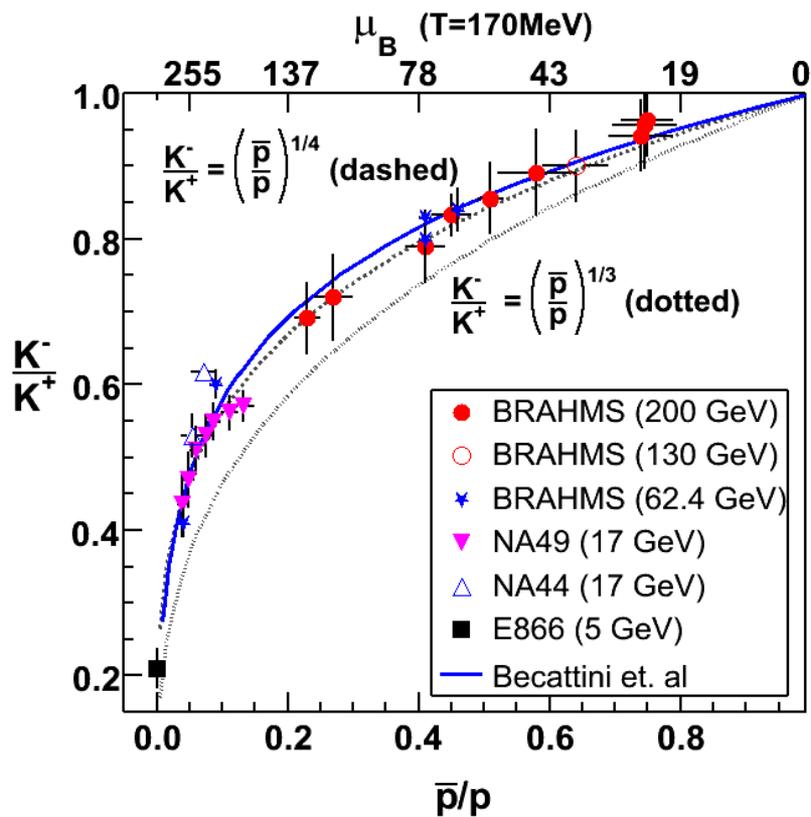

pions

pions

K-/K⁺ and antihyperon/hyperon

$$K^-/K^+ = \exp((2\mu_s - 2\mu_{u,d})/T)$$

$$p\bar{b}/p = \exp(-6\mu_{u,d}/T)$$

$$\mu_s=0 \Rightarrow K^-/K^+ = (p\bar{b}/p)^{1/3}$$

$$\text{Fit shows that } K^-/K^+ = (p\bar{b}/p)^{1/4}$$

$$\Rightarrow \mu_s = 1/4 \mu_{u,d}$$

How $\mu_s = 1/4 \mu_{u,d}$ will work for hyperons?

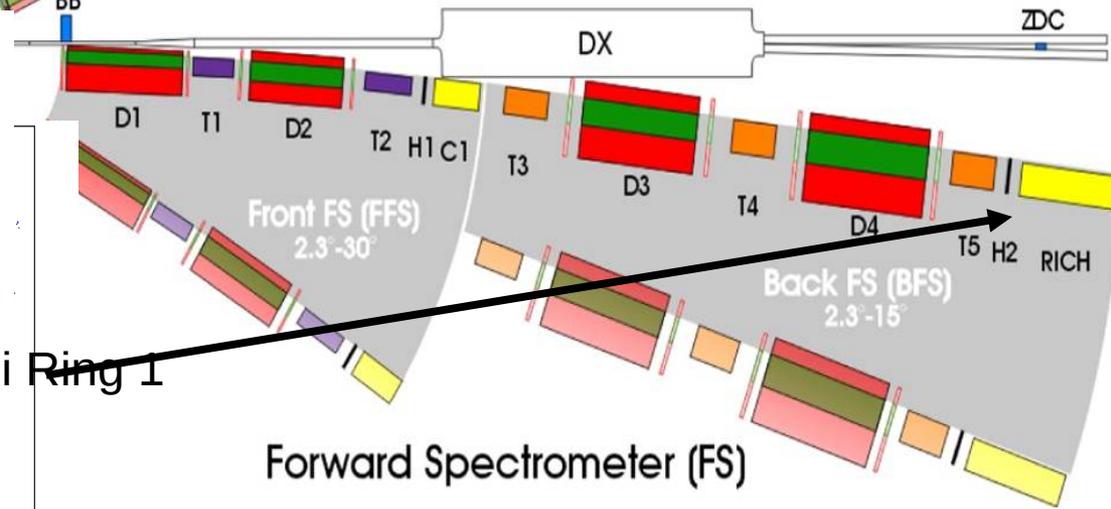

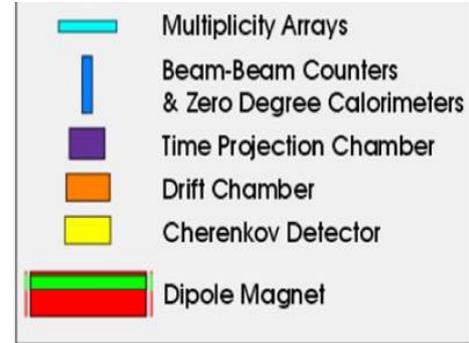

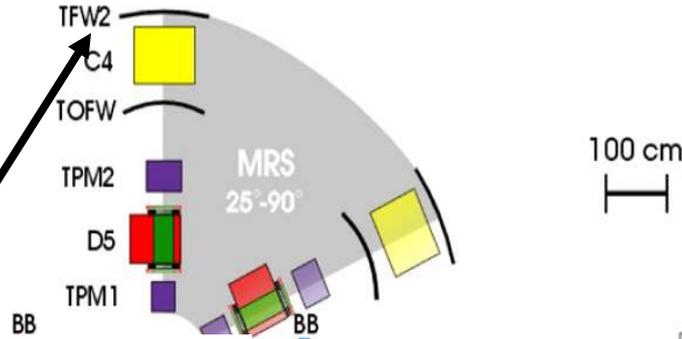

$$H\bar{b}/H = (p\bar{b}/p)^{3/4} \text{ for } \Lambda$$

$$= (p\bar{b}/p)^{1/2} \text{ for } \Xi$$

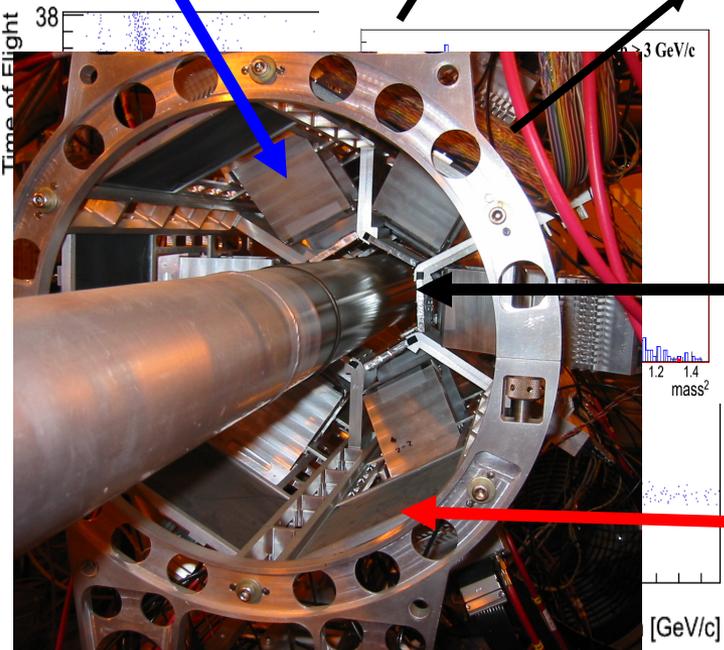

$$= (p\bar{b}/p)^{1/4} \text{ for } \Omega$$
